THERMAL AGITATION OF ELECTRIC CHARGE IN CONDUCTORS*

By H. Nyquist

Abstract

The electromotive force due to thermal agitation in conductors is calculated by means of principles in thermodynamics and statistical mechanics. The results obtained agree with results obtained experimentally.

 $\mathbf{D}^{\mathrm{R. J. B. JOHNSON^1}}$ has reported the discovery and measurement of an electromotive force in conductors which is related in a simple manner to the temperature of the conductor and which is attributed by him to the thermal agitation of the carriers of electricity in the conductors. The work to be resported in the present paper was undertaken after Johnson's results were available to the writer and consists of a theoretical deduction of the electromotive force in question from thermodynamics and statistical mechanics.²

Consider two conductors each of resistance R and of the same uniform

temperature T connected in the manner indicated in Fig. 1. The electromotive force due to thermal agitation in conductor I causes a current to be set up in the circuit whose value is obtained by dividing the electromotive force by 2R. This current causes a heating or absorption of power in conductor II, the absorbed power being equal to the product of Rand the square of the current. In other words power is transferred from conductor I to conductor II. In

precisely the same manner it can be deduced that power is transferred from conductor II to conductor I. Now since the two conductors are at the same temperature it follows directly from the second law of thermodynamics that the power flowing in one direction is exactly equal to that flowing in the other direction. It will be noted that no assumption has been made as

Power spectral density of the electric noise

 $|\tilde{\eta}|^2 = 4k_B R T$

In 1928 well before Fluctuation Dissipation Theorem (FDT), this was the second example, after the Einstein relation for Brownian motion, relating the dissipation of a system to the amplitude of the thermal noise.

What are the consequences of removing the Nyquist equilibrium conditions ?

What are the statistical properties of the energy exchanged between the two conductors kept at different temperature ?

We analyse these questions in an electric circuit within the framework of FT.

How the variance of V₁ and V₂ are modified because of the heat flux ?

What is the role of correlation between V₁ and V₂?

 $\tau_o \simeq 0.01 s$

 $\tau_o \simeq 0.01 s$

On the entropy produced by thermal fluctuations

$$\Delta S_{r,\tau} = Q_{1,\tau} / T_1 + Q_{2,\tau} / T_2$$

related to the heat exchanged with the reservoirs

Following Seifert, (PRL 95, 040602, 2005) who developed this concept for a single heat bath, we introduce a trajectory entropy for the evolving system

 $S_s(t) = -k_B \log P(V_1(t), V_2(t))$

and the entropy production on the time $\boldsymbol{\tau}$

$$\Delta S_{s,\tau} = -k_B \log \left[\frac{P(V_1(t+\tau), V_2(t+\tau))}{P(V_1(t), V_2(t))} \right]$$

The total entropy is :

$$\Delta S_{tot,\tau} = \Delta S_{r,\tau} + \Delta S_{s,\tau}$$

Summary of the experimental and theoretical results "On the heat flux and entropy produced by thermal fluctuations"

- The mean heat flux $\langle \dot{Q} \rangle \propto (T_2 T_1)$
- The pdf of $W_m / \langle W_m \rangle$ satisfies an asymptotic FT whose prefactor is the entropy production rate $\langle W_m \rangle (1/T_m 1/T_{m'})$.
- The out of equilibrium variance : $\sigma_m^2(T_m, T_{m'}) = \sigma_{m,eq}^2(T_m) + \langle \dot{Q}_m \rangle R_m$ (Extension of Harada-Sasa relation)
- The total entropy ΔS_{tot} satisfies a conservation law which implies the second law and imposes the existence of a FT which is not asymptotic in time.
- ΔS_{tot} is rigorously zero in equilibrium, both in average and fluctuations
- The electrical-mechanical analogy makes these results very general and useful

On the heat flux and entropy produced by thermal fluctuations Theory

 q_m is the charge flowed in the resistance R_m

$$q_1 = (V_1 - V_2) C + V_1 C_1$$

$$q_2 = (V_1 - V_2) C - V_2 C_2$$

$$R_1 \dot{q}_1 = -q_1 \frac{C_2}{X} + (q_2 - q_1) \frac{C}{X} + \eta_1$$
$$R_2 \dot{q}_2 = -q_2 \frac{C_1}{X} + (q_1 - q_2) \frac{C}{X} + \eta_2$$

$$\langle \eta_i(t)\eta_j(t')\rangle = 2\delta_{ij}k_BT_iR_j\delta(t-t')$$

On the heat flux bewteen two particles at two different temperature

Energy flow between two hydrodynamically coupled particles kept at different effective temperatures A. Bérut, A. Petrosyan and S. Ciliberto, EPL, 107 (2014) 60004

Two Brownian particles trapped by two laser beams.

Difficulty of having an harmonic coupling between the particles. The main source of coupling is hydodynamic (viscous)

The temperature gradient is done by forcing the motion of one particle with an external random force

Variances and cross variances as a function of the random driving voltage (force) at

$$d = 3.2 \,\mu \mathrm{m}$$

Variances and cross variances as a function of the distance betwen the beads for a fixed driving of 1.5V

From a suitable hydrodynamic model one can compute the variances

$$\sigma_{11}^2 = \langle x_1 x_1 \rangle = \frac{k_{\rm B}(T + \Delta T)}{k_1} - \frac{k_2}{k_1} \frac{\epsilon^2 k_{\rm B} \Delta T}{k_1 + k_2}$$

$$\sigma_{12}^2 = \langle x_1 x_2 \rangle = \frac{\epsilon k_{\rm B} \Delta T}{k_1 + k_2}$$

$$\sigma_{22}^2 = \langle x_2 x_2 \rangle = \frac{k_{\rm B} T}{k_2} + \frac{\epsilon^2 k_{\rm B} \Delta T}{k_1 + k_2}$$

where :

ENS DE LYON

 ϵ is the coupling coefficient of the particle. It has to depend on the distance but not on the random driving amplitude

 ΔT is the temperature difference induced by the random driving.

 k_1 and k_2 are the stiffness of the optical traps.

From a suitable hydrodynamic model one can compute the variances

$$\sigma_{11}^2 = \langle x_1 x_1 \rangle = \frac{k_{\rm B}(T + \Delta T)}{k_1} - \frac{k_2}{k_1} \frac{\epsilon^2 k_{\rm B} \Delta T}{k_1 + k_2}$$

$$\sigma_{12}^2 = \langle x_1 x_2 \rangle = \frac{\epsilon k_{\rm B} \Delta T}{k_1 + k_2}$$

$$\sigma_{22}^2 = \langle x_2 x_2 \rangle = \frac{k_{\rm B} T}{k_2} + \frac{\epsilon^2 k_{\rm B} \Delta T}{k_1 + k_2}$$

where :

ENS DE LYON

 $\epsilon,\,T$ and ΔT are the unknown

 ϵ is the coupling coefficient of the particle. It has to depend on the distance but not on the random driving amplitude

 ΔT is the temperature difference induced by the random driving.

 k_1 and k_2 are the stiffness of the optical traps.

Bead 1 has an effective temperature $T^* = T + \Delta T$

The standard hydrodynamic model

It follows that the system of equations is:

$$\begin{cases} \gamma \dot{x}_1 = -k_1 x_1 + \epsilon (-k_2 x_2 + f_2) + f_1 + f^* \\ \gamma \dot{x}_2 = -k_2 x_2 + \epsilon (-k_1 x_1 + f_1 + f^*) + f_2 \end{cases}$$

The standard hydrodynamic model

It follows that the system of equations is:

$$\begin{cases} \gamma \dot{x}_1 = -k_1 x_1 + \epsilon (-k_2 x_2 + f_2) + f_1 + f^* \\ \gamma \dot{x}_2 = -k_2 x_2 + \epsilon (-k_1 x_1 + f_1 + f^*) + f_2 \end{cases}$$

comparison with the electric case

$$R_1 \dot{q}_1 = -q_1 \frac{C_2}{X} + (q_2 - q_1) \frac{C}{X} + \eta_1$$
$$R_2 \dot{q}_2 = -q_2 \frac{C_1}{X} + (q_1 - q_2) \frac{C}{X} + \eta_2$$

Clair

- The differrence between out-equilibrium and equilibrium variance is proportional to the heat flux
- A hydrodynamic models precisely described the experimental data
- The FT seems to correctly estimate the effective temperature within experimental errors.
- The definition of heat is doubtful !
